

MAT 228A Theory Homework 2

Ivan Cherkashin

Problem 1

THEOREM. $\|f\|_2^2 = \|\hat{f}\|_2^2$, where \hat{f} is the discrete Fourier transform of f .

PROOF. Let \mathbb{C}^M inherit the structure of a Hilbert space from the inner product defined in equation (5). The discrete Fourier transform is a linear operator in this space:

$$(0.1) \quad \hat{f} = \begin{pmatrix} \langle f^h, w^{(k_1)} \rangle \\ \dots \\ \langle f^h, w^{(k_M)} \rangle \end{pmatrix} = F^* f$$

Fourier matrix $F = (w^{(k_1)} \dots w^{(k_M)})$ is unitary, since the column vectors of F form an orthonormal basis of \mathbb{C}^M . Naturally, the matrix F^* is also unitary. By definition, unitary operators preserve inner products and, therefore, norms:

$$(0.2) \quad \|\hat{f}\|_2^2 = \langle \hat{f}, \hat{f} \rangle = \langle F^* f, F^* f \rangle = \langle f, f \rangle = \|f\|_2^2$$

□

Problem 2

THEOREM. Prove that $\hat{f}^h = f^h$, where $\hat{f}^h = \sum_k \langle f^h, w^{(k)} \rangle w^{(k)}$

PROOF. Fourier matrix F is unitary: $FF^* = F^*F = I \implies$

$$(0.3) \quad \hat{f}^h = \sum_k \langle f^h, w^{(k)} \rangle w^{(k)} = (w^{(k_1)} \dots w^{(k_M)}) \begin{pmatrix} \langle f^h, w^{(k_1)} \rangle \\ \dots \\ \langle f^h, w^{(k_M)} \rangle \end{pmatrix} = FF^* f^h = f^h$$

The function

$$(0.4) \quad \hat{f}(x) = \sum_k \langle f^h, w^{(k)} \rangle w^{(k)}(x)$$

is infinitely differentiable, as a finite linear combination of infinitely differentiable functions, and is equal to the original function f at the grid points. Therefore, \hat{f} interpolates f (trigonometric interpolation). \square

Problem 3

LEMMA 0.1.

$$\overline{c_k} = c_{-k} \iff \sum_{|k| \leq n} c_k e^{2\pi i k x} \in \mathbb{R} \quad \forall x \in [0, 1]$$

SUFFICIENCY. Let $\overline{c_k} = c_{-k}$, $|k| \leq n$. Then

$$S_n = \sum_{|k| \leq n} c_k e^{2\pi i k x} = c_0 + \sum_{k=1}^n (c_k e^{2\pi i k x} + c_{-k} e^{-2\pi i k x}) = c_0 + \sum_{k=1}^n (c_k e^{2\pi i k x} + \overline{c_k e^{2\pi i k x}})$$

which is invariant under complex conjugation:

$$\overline{S_n} = S_n \implies S_n \in \mathbb{R}$$

\square

NECESSITY. Let $S_n \in \mathbb{R}$ Then

$$S_n - \overline{S_n} = 0 \iff \sum_{|k| \leq n} (c_k - \overline{c_{-k}}) e^{2\pi i k x} = 0$$

Since $e^{2\pi i k x}$ are linearly independent, the identity holds for all x if and only if

$$c_k - \overline{c_{-k}} = 0$$

\square

(a). Since

$$\hat{f}(x) = \sum_{-\frac{M}{2} < k \leq \frac{M}{2}} c_k e^{2\pi i k x} = \sum_{|k| \leq \frac{M}{2}} c_k e^{2\pi i k x} - c_{-\frac{M}{2}} e^{-M\pi i x} = \Sigma(x) + r(x)$$

and since $\Sigma(x) \in \mathbb{R}$, by the lemma, and, $r(x) \in \mathbb{C}$,

$$S(x) + r(x) = \hat{f}(x) \in \mathbb{C}$$

i.e. the interpolation is not strictly real-valued (N must be odd in order to obtain real-valued trigonometric interpolation in the complex form).

(b). Let $\hat{f}(x)$ be strictly real-valued. Then

$$\hat{f}(x) - \overline{\hat{f}(x)} = \sum_{k \leq M-1} (c_k e^{2\pi i k x} - \overline{c_k} e^{-2\pi i k x}) \equiv 0 \iff c_k = 0$$

since complex exponents with different wavenumbers k are linearly independent.

But then $\hat{f}(x) \equiv 0$, which means that $\hat{f}(x)$ is, in general, complex.

Problem 4**(a).**THEOREM. *Compute the symbol for the downwind method:*

$$(Lu)_i = u_i^n + \sigma(u_i^n - u_{i+1}^n)$$

PROOF.

$$L = \sum_{s=0}^1 c_s S^s = 1 + \sigma(1 - S^1) = (1 + \sigma) - \sigma S^1$$

The symbol is

$$\lambda(\beta) = \sum_{s=0}^1 c_s e^{i\beta s} = (1 + \sigma) - \sigma e^{i\beta}$$

□

(b).THEOREM. *Find amplification factors for all modes, $k \in [-\frac{M}{2} + 1, \frac{M}{2}]$* PROOF. The amplification factor for k -th mode is $|\lambda(\beta(k))|$.

$$\begin{aligned} (0.5) \quad |\lambda(\beta)|^2 &= \lambda(\beta) \overline{\lambda(\beta)} = ((1 + \sigma) - \sigma e^{i\beta})((1 + \sigma) - \sigma e^{-i\beta}) = \\ &= (1 + \sigma)^2 + \sigma^2 - 2\sigma(1 + \sigma) \cos \beta = 1 + 2\sigma(1 + \sigma)(1 - \cos \beta) \\ &\implies |\lambda(\beta(k))| = \sqrt{1 + 2\sigma(1 + \sigma)(1 - \cos 2\pi kh)} \end{aligned}$$

Thus, *all modes are amplified* except

$$\cos \beta(k) = \cos 2\pi kh = 0 \iff k = 0$$

Since almost all modes are amplified by the finite difference operator, the downwind method is inherently unstable.

□

Problem 5**(a).**THEOREM. *Lax-Friedrichs method is stable in L^2 norm.*

PROOF. The symbol of Lax-Friedrichs finite difference operator is:

$$L = \sum_{s=-1}^1 c_s S^s = \frac{1}{2}(S^{-1} + S^1) + \frac{\sigma}{2}(S^{-1} - S^1) \implies$$

$$\begin{aligned} (0.6) \quad \lambda(\beta) &= \frac{1}{2}(e^{i\beta} + e^{-i\beta} - \sigma(e^{i\beta} - e^{-i\beta})) = \cos \beta - i\sigma \sin \beta \implies \\ |\lambda(\beta)|^2 &= \cos^2 \beta + \sigma^2 \sin^2 \beta = 1 - (1 - \sigma^2) \sin^2 \beta \end{aligned}$$

$$\max_{\beta} |\lambda(\beta)| \leq 1 \iff \sigma \in [0, 1]$$

Thus, by spectral stability criterion, Lax-Friedrichs method is stable in L^2 norm whenever $\sigma \in [0, 1]$ □

(b).

THEOREM. *Lax-Friedrichs method is consistent.*

PROOF. The local truncation error is:

$$\tau_i^n = \frac{u_i^{n+1} - (Lu^n)_i}{\Delta t} = \frac{1}{\Delta t} \left(u_i^{n+1} - \frac{1+\sigma}{2} u_{i-1}^n - \frac{1-\sigma}{2} u_{i+1}^n \right)$$

It is convenient to represent the values of a function and its derivatives in operator form, as a vector in which the n -th component is $(n-1)$ -th term of the Taylor series (i.e. as k -jets, where $k=2$ in our case, i.e. up to the first derivative).

Thus,

$$\frac{u_i^{n+1}}{\Delta t} = \begin{pmatrix} 1 + O(\Delta t) \\ \partial_t \end{pmatrix}, \quad \frac{u_{i-1}^n}{\Delta t} = \begin{pmatrix} 1 + O(h) \\ -\frac{a}{\sigma} \partial_x \end{pmatrix}, \quad \frac{u_{i+1}^n}{\Delta t} = \begin{pmatrix} 1 + O(h) \\ \frac{a}{\sigma} \partial_x \end{pmatrix}$$

and

$$\tau_i^n = \left(1 - \left(\frac{1+\sigma}{2} + \frac{1-\sigma}{2} \right) + O(\Delta t) \right) = \begin{pmatrix} O(\Delta t) \\ \partial_t + a \partial_x \end{pmatrix} = O(\Delta t)$$

Due to triangle inequality for norms,

$$(0.7) \quad \|\tau^n\| = \frac{\|u^{n+1} - (Lu^n)\|}{\Delta t} \leq \max_i |\tau_i^n| = O(\Delta t) \quad \|\tau^n\| = O(\Delta t) \longrightarrow 0, \quad t \longrightarrow 0$$

Thus, Lax-Friedrichs method is consistent. □

(c).

THEOREM. *Lax-Friedrichs method converges to the exact solution of the linear transport equation.*

PROOF. Convergence of a consistent stable linear finite difference method is essentially the consequence of triangle inequality property of norms, the definition of an operator norm which implies $\|Lx\| \leq \|L\|\|x\|$, the fact that $\|L\| \leq 1$ for stable Lax-Friedrichs operator, and, finally, linearity of the latter:

(0.8)

$$\begin{aligned}
\|u(t^n) - u^n\| &= \|u(t^n) - Lu^{n-1}\| = \|u(t^n) - Lu(t^{n-1}) + Lu(t^{n-1}) - Lu^{n-1}\| \leq \\
&\leq \|u(t^n) - Lu(t^{n-1})\| + \|Lu(t^{n-1}) - Lu^{n-1}\| \leq \\
&\leq \|u(t^n) - Lu(t^{n-1})\| + \|L(u(t^{n-1}) - u^{n-1})\| \leq \\
&\leq \|u(t^n) - Lu(t^{n-1})\| + \|L\| \|u(t^{n-1}) - u^{n-1}\| \leq \\
&\leq \|u(t^n) - Lu(t^{n-1})\| + \|u(t^{n-1}) - u^{n-1}\|
\end{aligned}$$

Since Lax-Friedrichs is consistent and its truncation error is $O(\Delta t)$

$$(0.9) \quad \|u(t^n) - Lu(t^{n-1})\| = O(\Delta t^2) \implies$$

$$\|u(t^n) - u^n\| = O(\Delta t^2) + \|u(t^{n-1}) - u^{n-1}\|$$

Since $\|u(t^n) - u^n\|$ is defined recursively through $\|u(t^{n-1}) - u^{n-1}\|$, by induction we find that

$$\|u(t^n) - u^n\| = O(N\Delta t^2) + \|u(t^0) - u^0\| = O(\Delta t)$$

Thus, consistency and stability imply *first-order* convergence of Lax-Friedrichs method:

$$\|u(t^n) - u^n\| \longrightarrow 0, \quad \Delta t \longrightarrow 0$$

□
